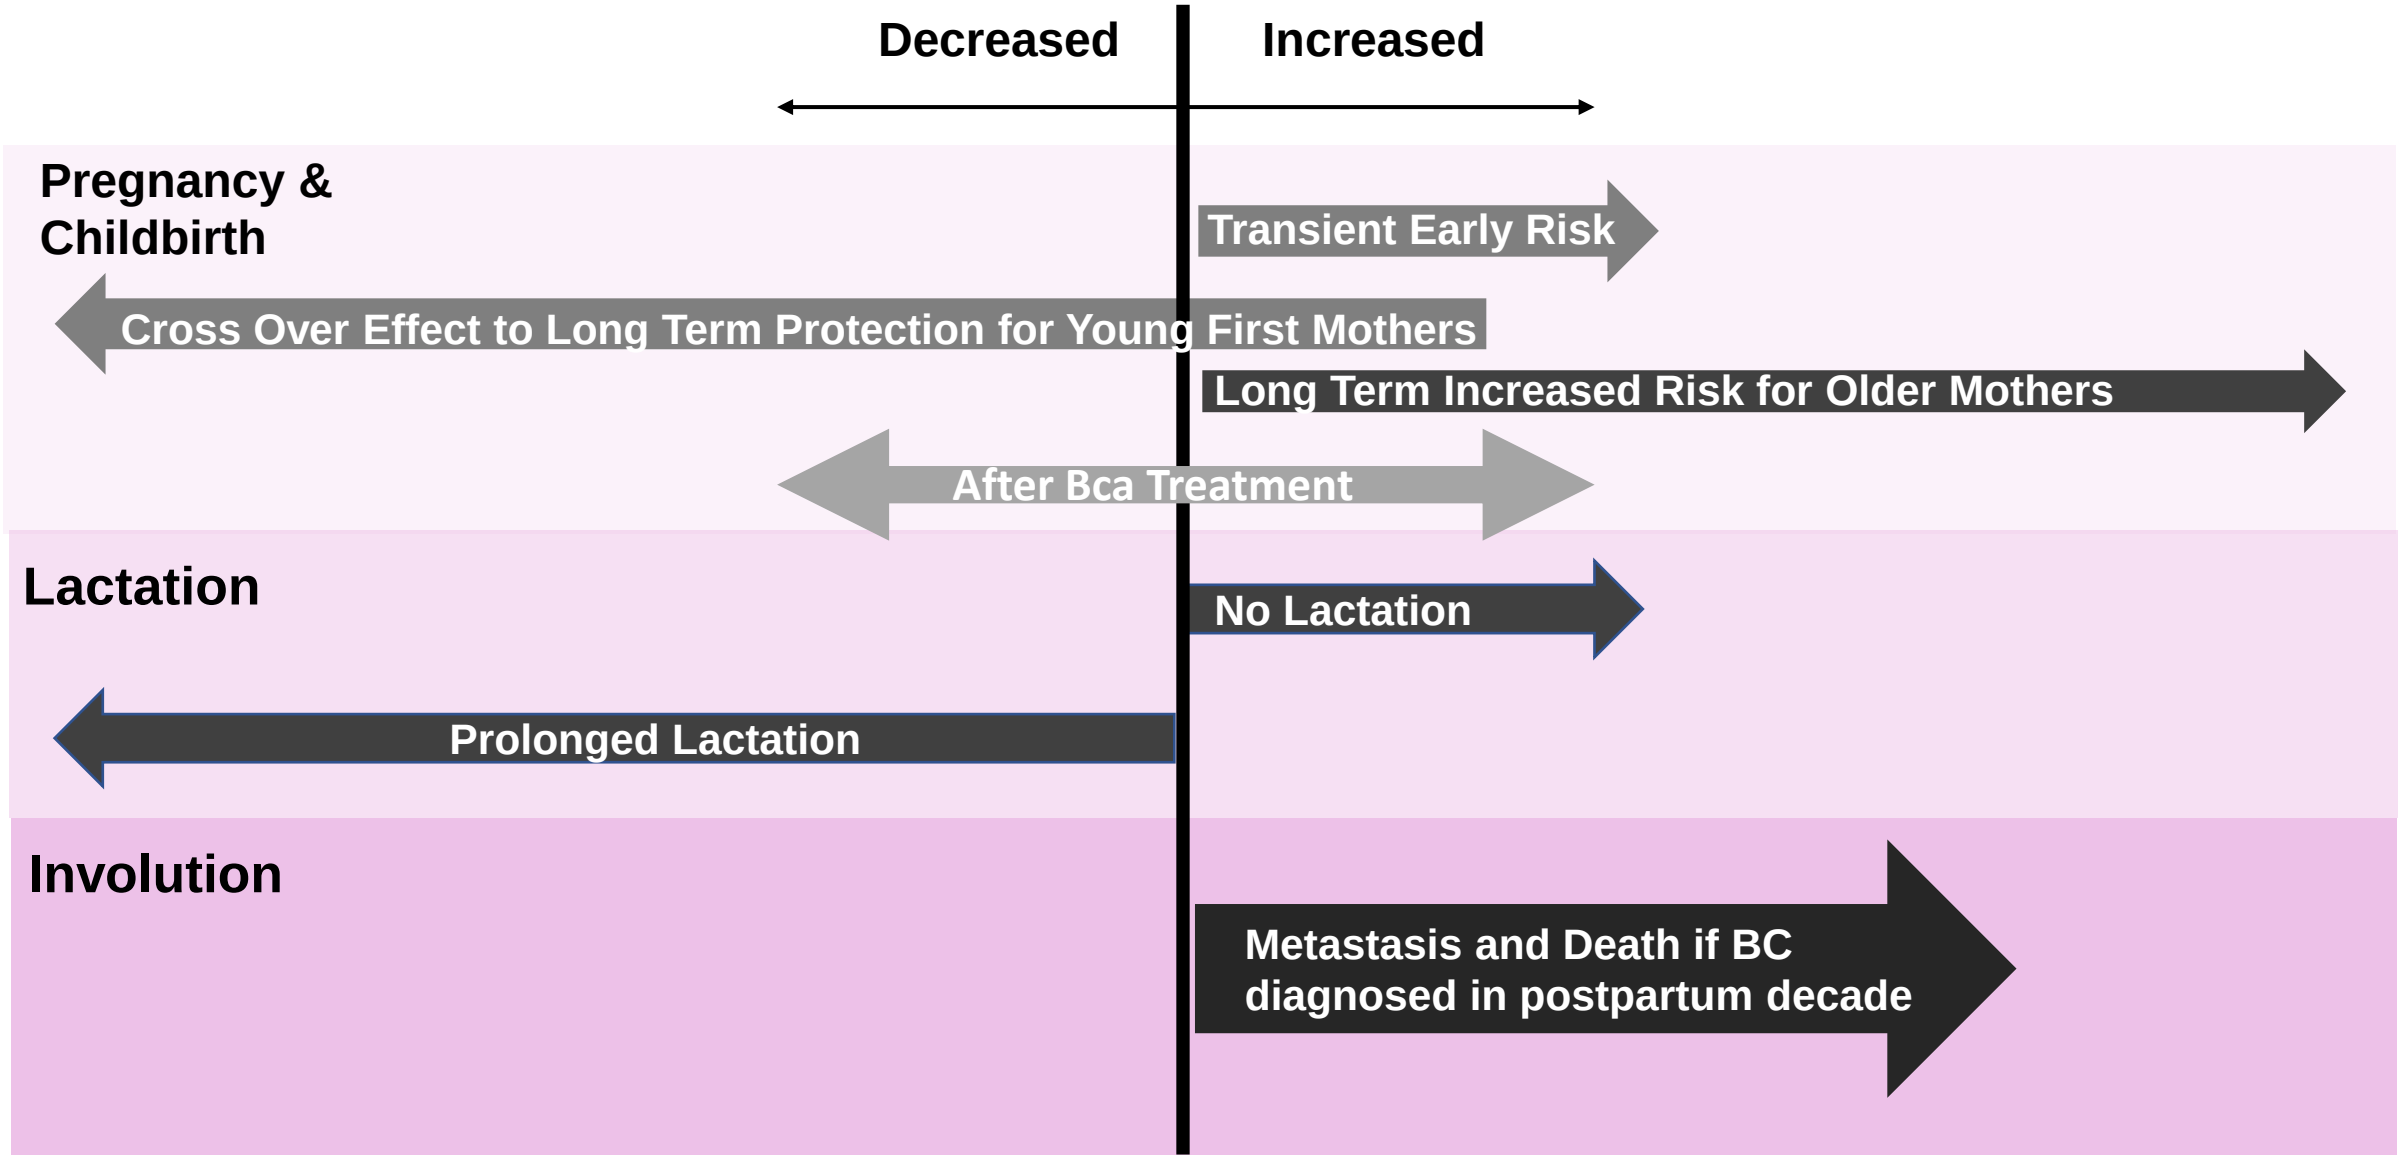
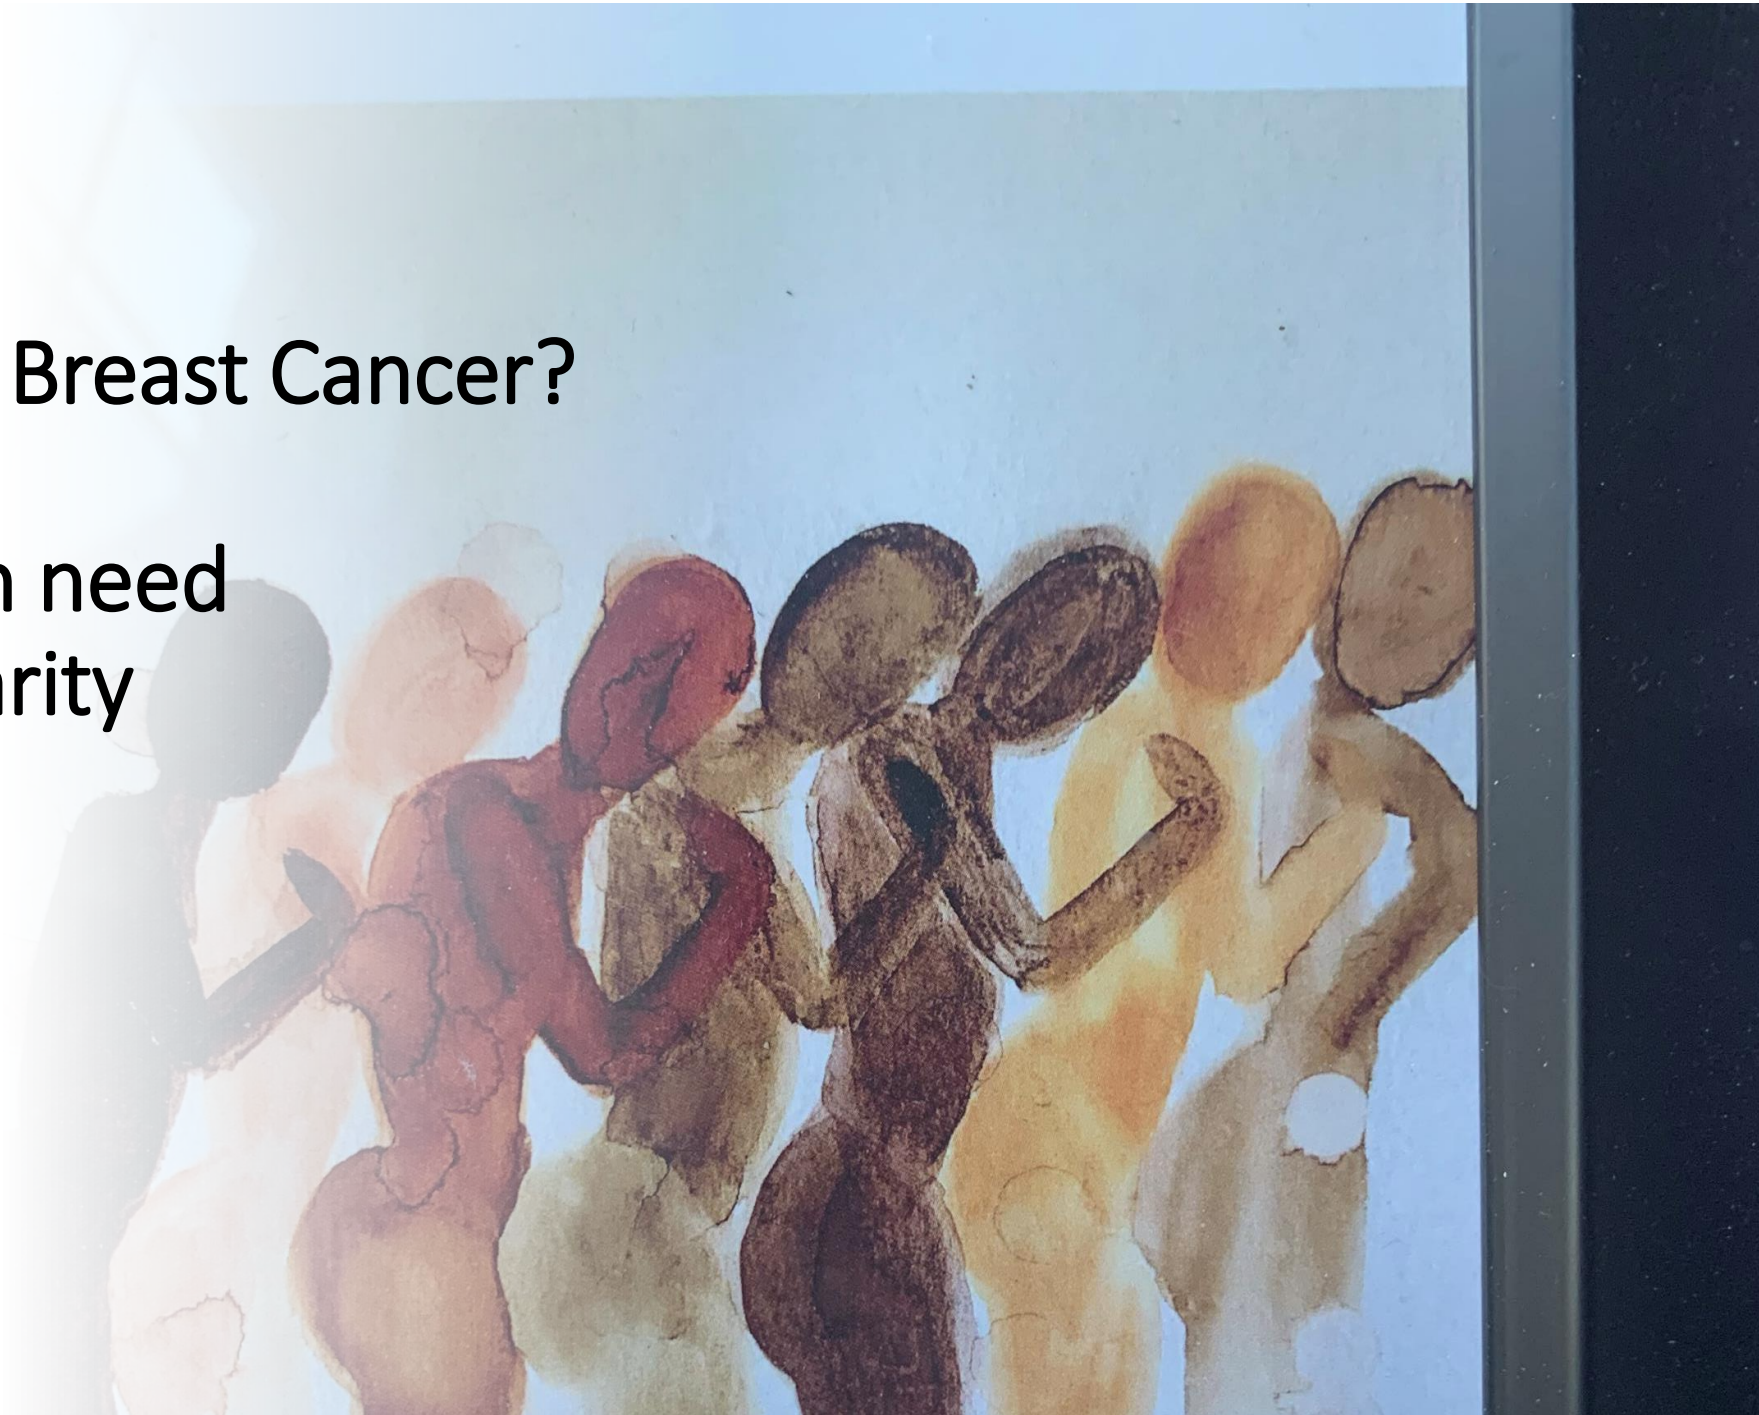
Breast Cancer Risk Over Time



What is Postpartum Breast Cancer?

Global unmet health need
Cancer of high disparity



University of Colorado
Cancer Center
Young Women's Breast Cancer
Translational Program

What is Postpartum Breast Cancer?

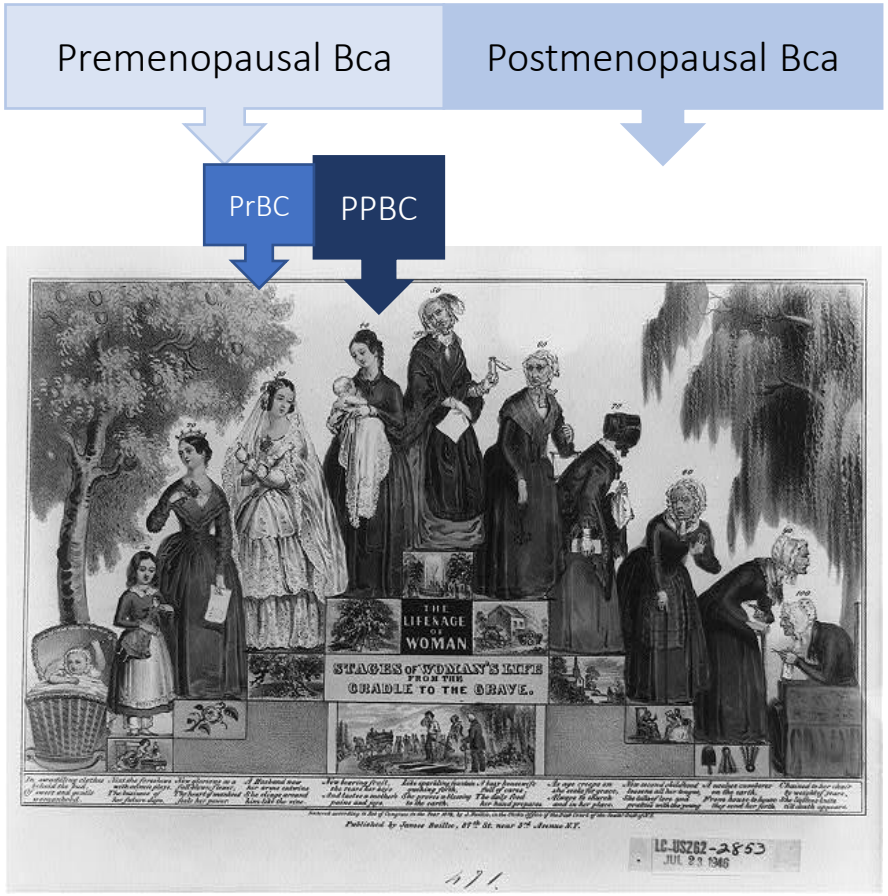
* Women diagnosed within 10 years of last childbirth
  estimation of 150,000 women/year, Globally
  32,000 women ≤45, 18,000 are PPBC/year in the US

* Higher likelihood for metastatic recurrence and death

*The cancers themselves are more aggressive and have less response to current treatments

* The incidence is increasing worldwide

Life windows of BCA Risk



Childbirth is a Risk Factor for Young Women's Breast Cancer

Diagnosis during early motherhood is a postpartum breast cancer

Studying breast cancer by the menopause divide dilutes YWBC/PPBC data

We treat our women under 45 based on results from pivotal trials where they are often ~10% representation.

Postpartum Diagnosis of Breast Cancer Independently Predicts for Poor Metastasis Free and Overall Survival

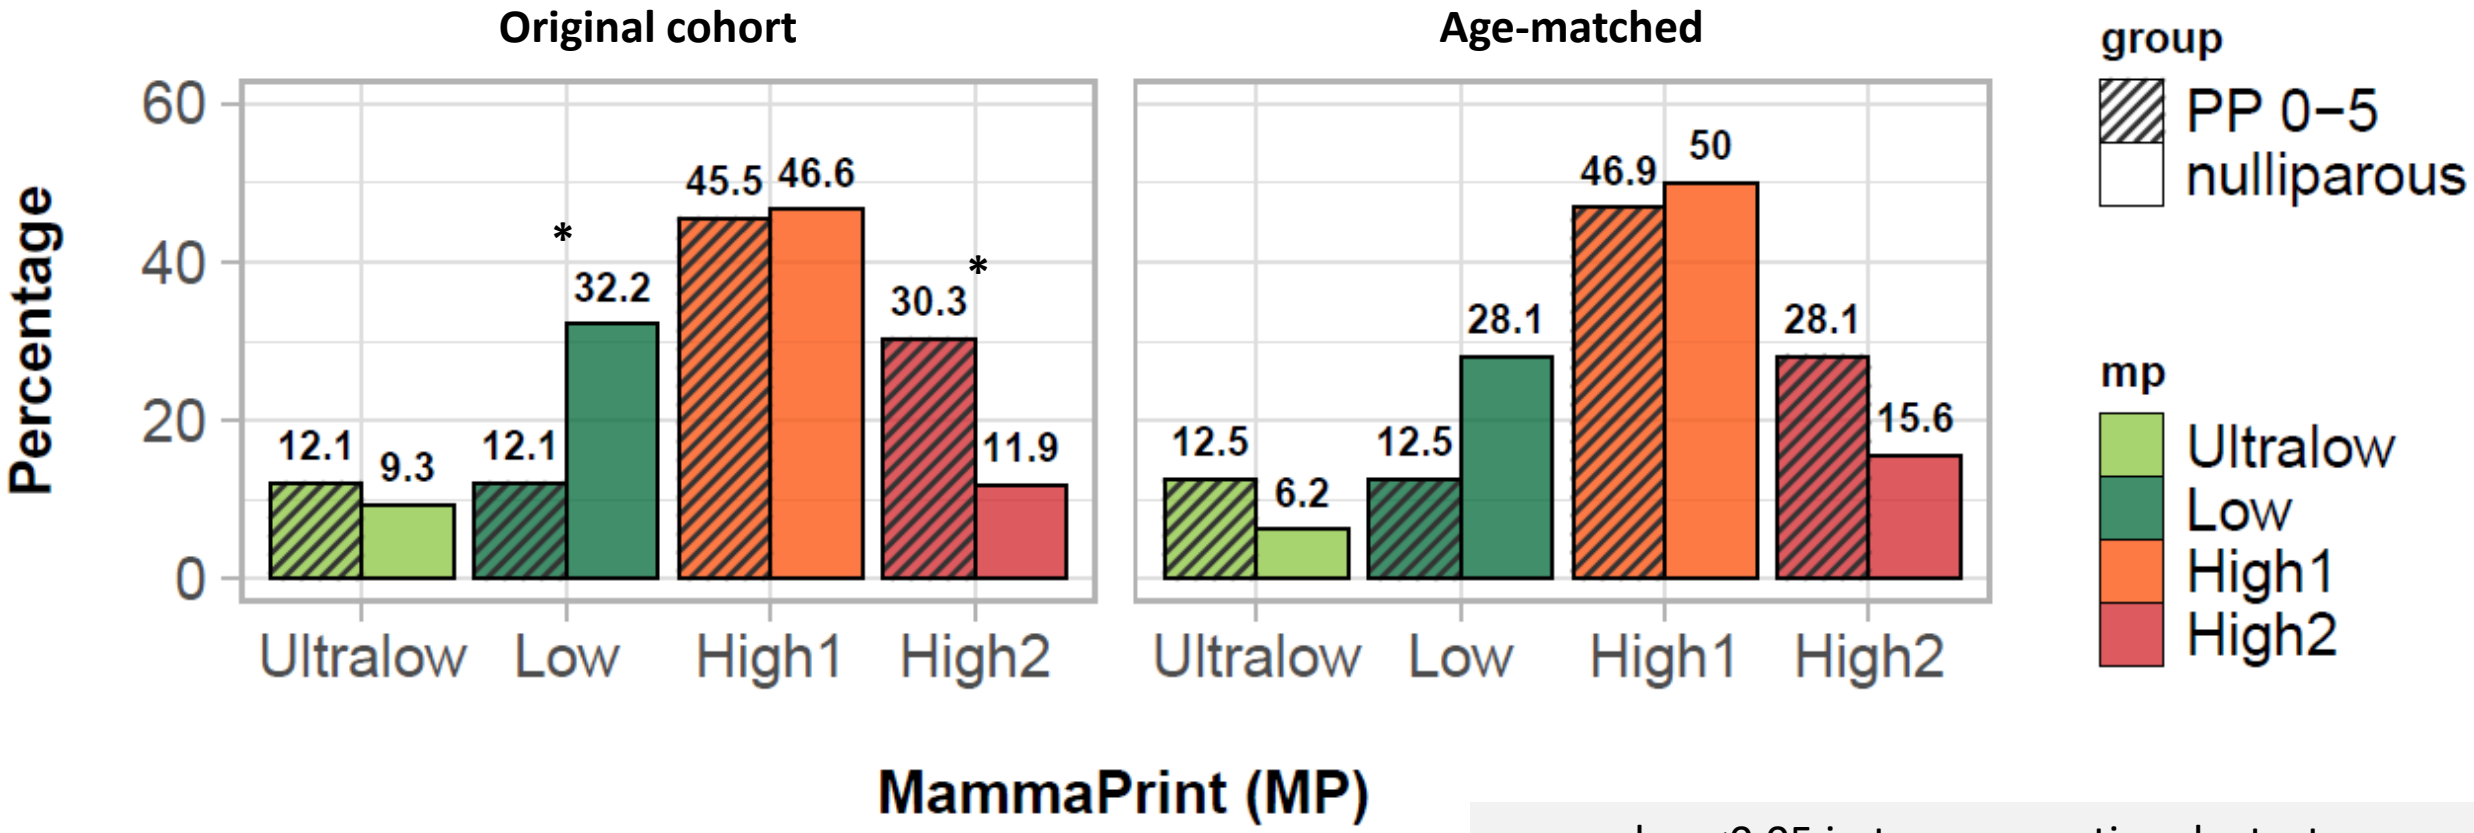
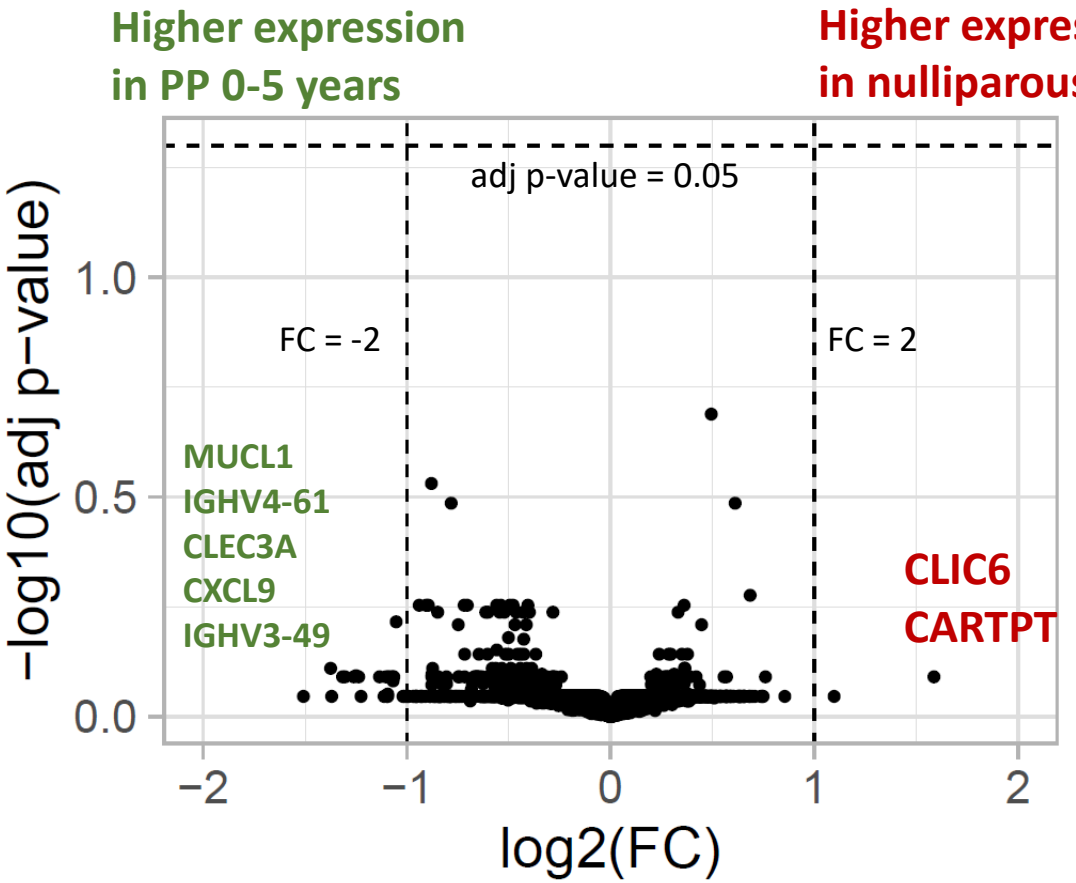
MammaPrint risk groups from original and age-matched groups from PP 0-5 years and nulliparous



- p-value <0.05 in two proportional z-test
- We see similar pattern of % differences in age-matched group, does not reach statistical significance – potentially due to low numbers, n less than 10 in most groups

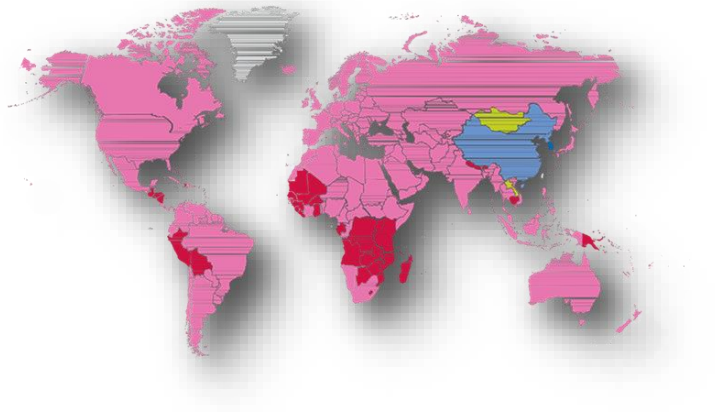
Borges, et al, ESMP Breast 2024

Whole transcriptome comparison in age-matched group – PP 0-5 years vs nulliparous



- No genes with significant difference adj pvalue < 0.05
- 2 genes have higher expression (FC >2) in nulliparous,
- 25 genes have higher expression (FC>2) in PP 0-5 years
  - Top 5 genes listed on the left

Borges, et al, ESMP Breast 2024



PrBC and PPBC are a global problem with disparity

- In 2020, there were 684,996 breast cancer deaths worldwide, with a disproportionally higher percentage affecting YWBC.
- The global mortality of breast cancer in women under age 50 is increasing fastest in parts of the world that have the least access to detection and treatment, East Asia & Pacific, Latin America & Caribbean, and all the African global regions.
- Notably, countries with the highest birth rates per 1000 people are also the same countries with the highest BC mortality < 50.
- PPBC is likely to increase and most so in countries where mortality is the highest
- Concurrent with this data and since 2021 alone, reports of higher risk for postpartum breast cancer have been reported.
  - Mexico, Northern Europe and Canada, Japan, Sub-Sahara African, Korea, Southern India and Singapore.

Thus, PPBC has gained international recognition as
a ***poor-prognostic subset of breast cancer of high unmet need***.

Amant et al, Lancet Oncology, 2021 and ESMO guidelines 2023!

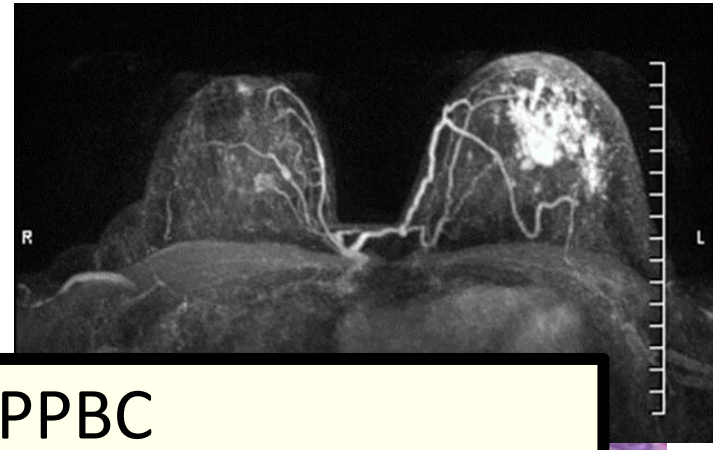
Parity and Breast Cancer Epidemiology

YWBC at diagnosis

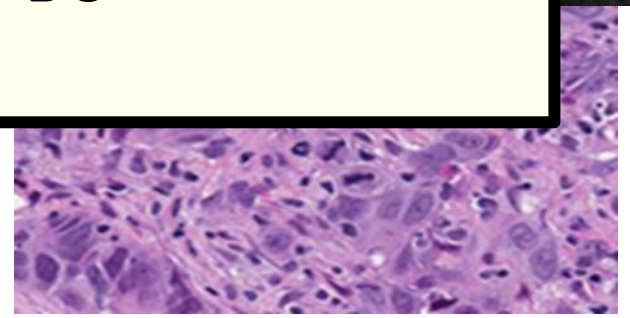
Nulliparous	Pregnant	Postpartum	Later Parous
Never pregnant or prior Incomplete pregnancy	Treatment initiated during pregnancy Trimester separation	Up to 5-10 years	>10 year post childbirth

Parity and Breast Cancer Epidemiology

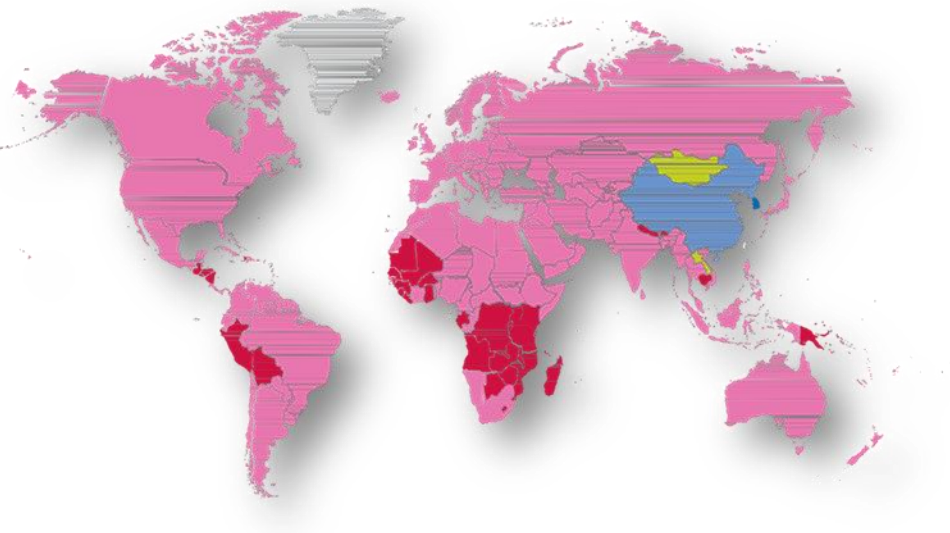
Goals of the Strategy



Reduce the mortality of YWBC/PPBC
Reduce the incidence of PPBC



Feasibility, Safety and Biomarker Clinical Study for the Prevention of Postpartum Breast Cancer



The next prevention drug?

Feasible
Cost-effective
Global applicability
Safety - No breast milk excretion
Acceptability
Efficacious

USA CDC National Survey of Family Growth 2015-2019 (https://www.cdc.gov/nchs/nsfg/index.htm):
77% of Black women are < 25 years of age at first birth
51% of White women are < 25 years of age at first pregnancy

Raju TN. Achieving healthy people 2030 breastfeeding targets in the United States: challenges and opportunities. Journal of Perinatology. 2023 Jan;43(1):74-80.

Aim

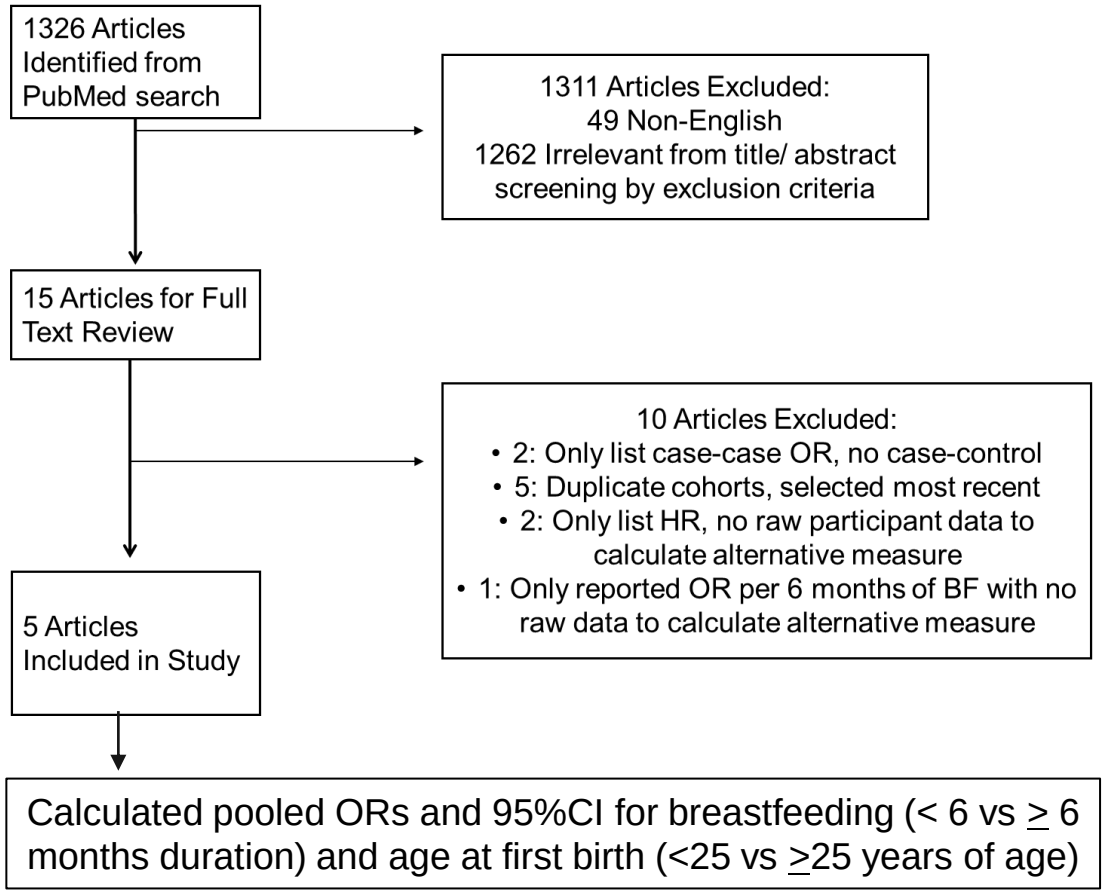
To determine to what extent differences in the prevalence of reproductive risk factors contribute to differences in TNBC incidence between Black and White women through calculating the population attributable fraction (PAF) of short breastfeeding duration and younger age at first birth

Population attributable fraction (PAF) is the proportion of disease that is due to a particular risk factor exposure in a population

Research Strategy

PubMed search inclusion criteria:

i) prospective cohort or case-control study in the US
ii) examine breastfeeding risk in relation to TNBC
iii) report odds ratio (OR), relative risk (RR), or hazards ratio (HR)



PAF Calculation

PAF = "PRF × (RR−1)" /"1+PRF ×(RR−1)"

PRF is the % population prevalence of a risk factor
- Breastfeeding estimates were from the **CDC's National Immunization Survey**
- Parity and age at first birth were from the **National Survey of Family Growth**

RR is relative risk approximated by pooled OR from the literature

Combined PAF = 1 – (1 – v(i)PAF1) × (1 – v(i)PAF2)) where
v(i)=1- r, and r is the polychoric correlation coefficient between breast feeding duration and age at first birth

Pooled Odds Ratios for TNBC risk and breastfeeding and age at first birth in Black and White women, respectively

		Risk Factors	
Subgroup		Breastfeeding <6 m	Age at first birth <25
White	**Pooled OR (95% CI)**	1.41(1.15,1.74)	1.06(0.86,1.29)
	I^2 %	67	84
	P^a	0.05	<0.01
Black	**Pooled OR (95% CI)**	1.35(1.06,1.73)	1.39(1.08,1.78)
	I^2 %	0	84
	P^a	0.59	0.01
Overall	**Pooled OR (95% CI)**	Common: 1.39(1.18,1.63) Random: 1.42(1.16,1.75)	Common: 1.19(1.01,1.39) Random: 1.19(0.84,1.69)
	I^2 %	38	81
	P^a	0.17	<0.01

I^2 = heterogeneity
Common = common effect mode, R package *meta*
Random = random effect model, R package *meta*

Population Attributable Risk for TNBC from breastfeeding, age at first birth, and combined in Black and White women, respectively

Risk Factor	White PAF (95% CI)	Black PAF (95% CI)
Breastfeeding < 6 m vs >= 6 m	12(5,20)	15(3,26)
Age at first birth <25	2(-6,11)	21(5,35)
Combined PAF	12	26.7

Conclusion

- We estimated that of all TNBC diagnosed in 2022, 4,850 (17% of 28,785 total) were attributable to breastfeeding shorter than 6 months and/or age at first birth younger than 25.
  - In 2022, **12% of TNBC in White women (n=2,421**) can be attributed to breastfeeding less than 6 months and/or age at first birth less than 25.
  - In 2022, **27% of TNBC in Black women (N=1,533**) can be attributed to breastfeeding less than 6 months and/or age at first birth less than 25.

- Policy changes aimed at supporting and more broadly enabling breastfeeding, addressing structural barriers, and promoting a culture shift could reduce the overall incidence and racial disparities in TNBC incidence in the USA.

- Increasing awareness of the protective role of breastfeeding, improving workplace policies, and limiting the lobbying power of formula companies might increase breastfeeding rates and duration leading to healthier infants and fewer breast cancers.

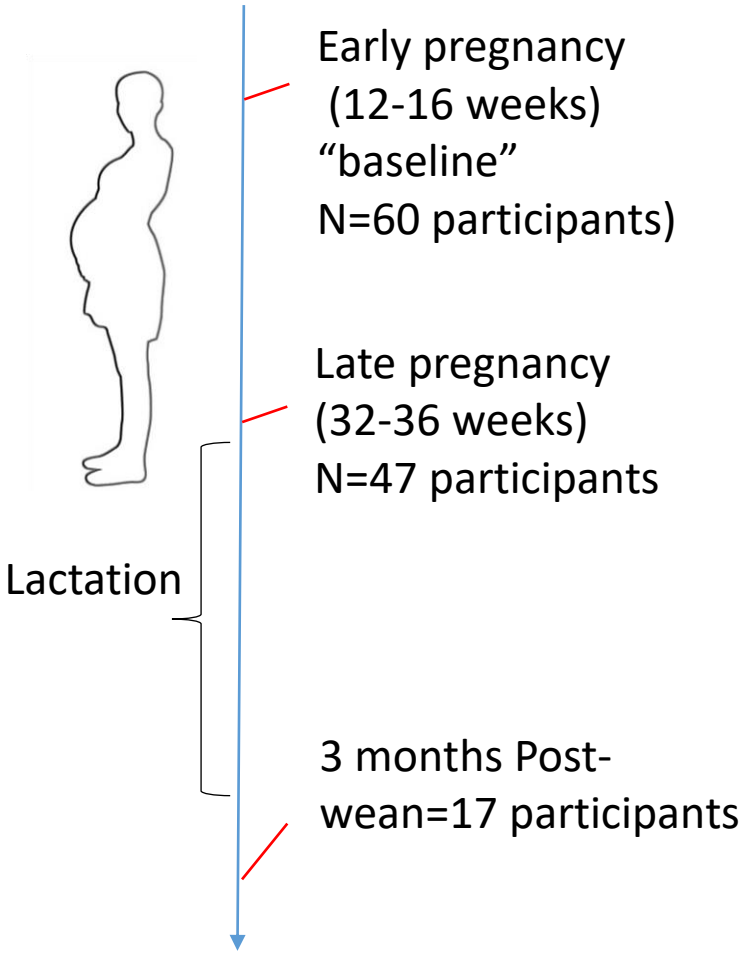
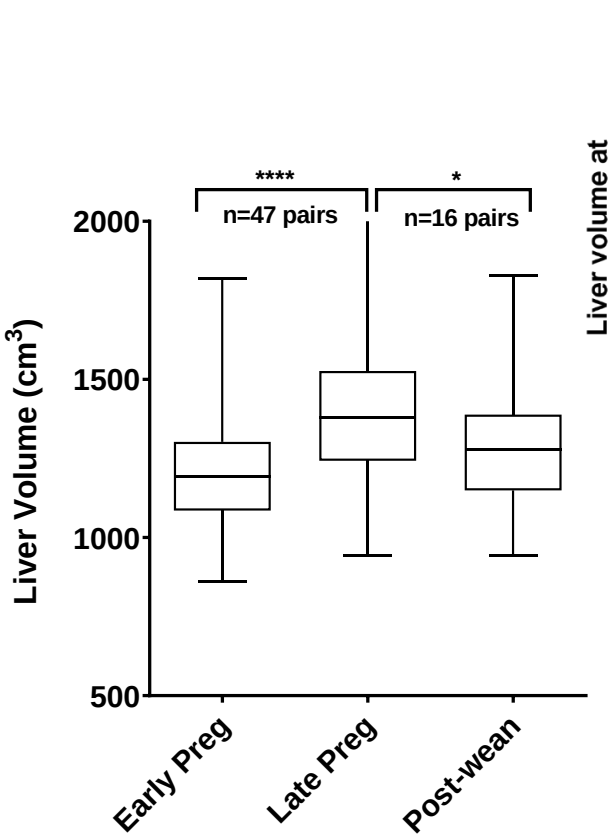
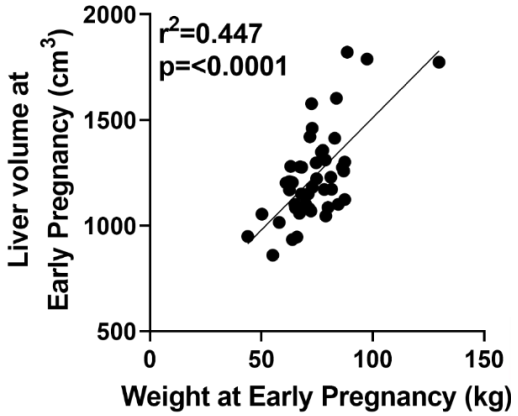
Evidence for Weaning-Induced Liver Involution in Women …..Metastatic Niche?

- Enroll women when they become pregnant;
- 2 study visits with optional post-weaning visit: MRI, blood, glucose tolerance tests

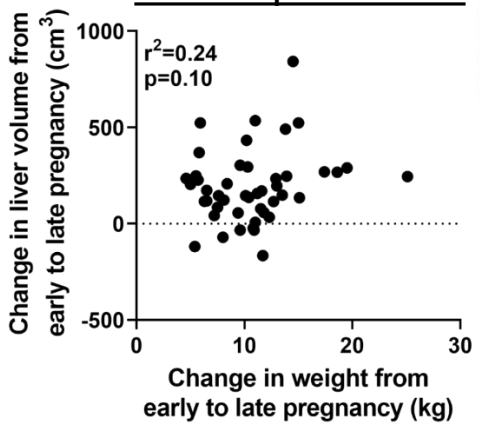




Hepatostasis



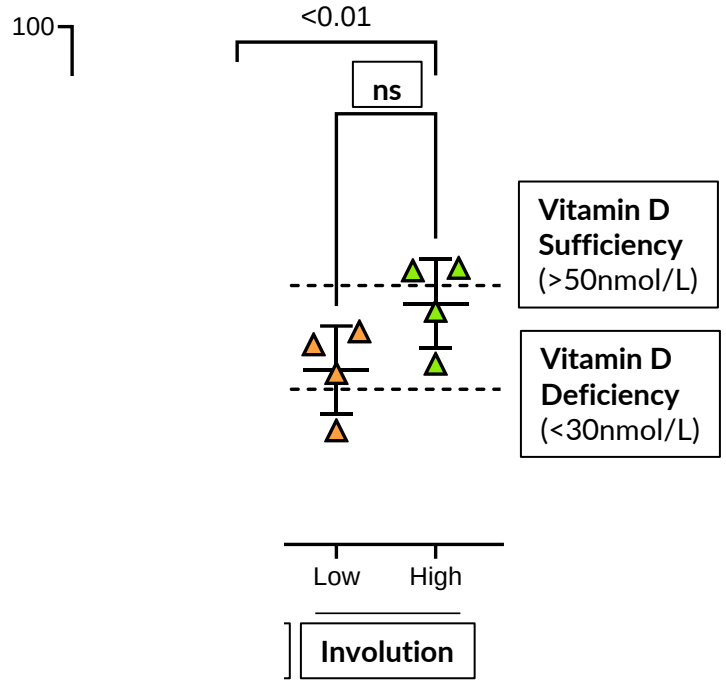
Not Hepatostasis



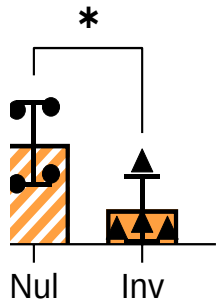
Bartlett et al, PNAS 2021

Vitamin D as Preventive and/or Therapeutic Agent for PPBC

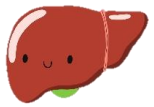
- Vitamin D deficiency associates with poor breast cancer outcomes
- Increased demand for vitamin D during pregnancy and lactation-
  - Vitamin D mobilizes bone calcium for fetal bone & milk
- Vitamin D deficiency is highly prevalent in postpartum women, ranging from 18-84%
- Vitamin D has immune-modulatory and anti-inflammatory activities-but efficacy in PPBC is unknown



ions of active form



Liver involution suppresses xenobiotic metabolism including Vit D

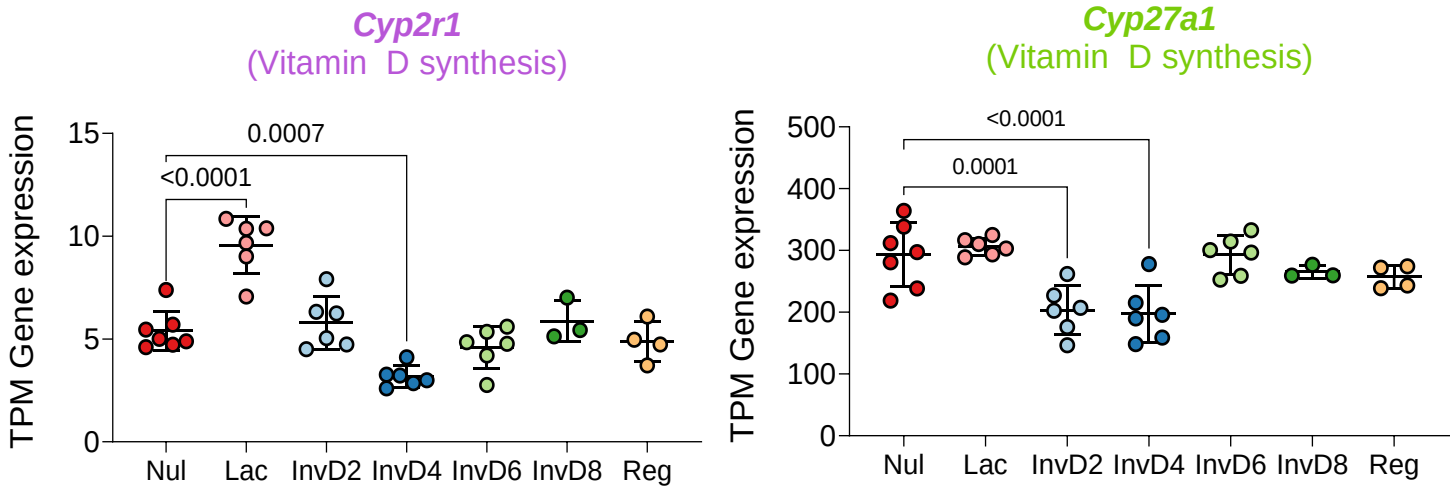


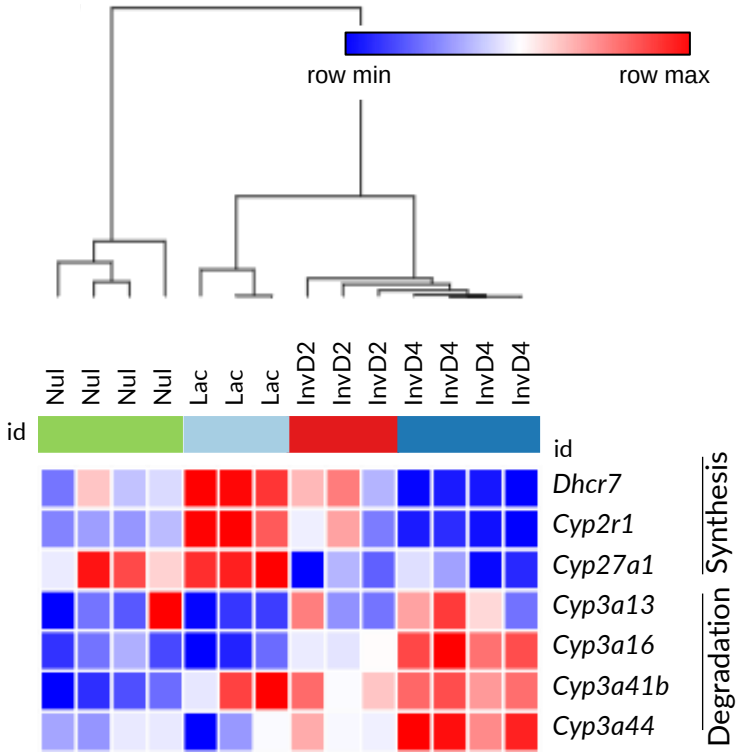
Cyp2r1 *Cyp27a1*

Vitamin D_3 → $25(OH)D_3$ → $1,25(OH)_2D_3$

(Dietary form) (circulating form) (active form)

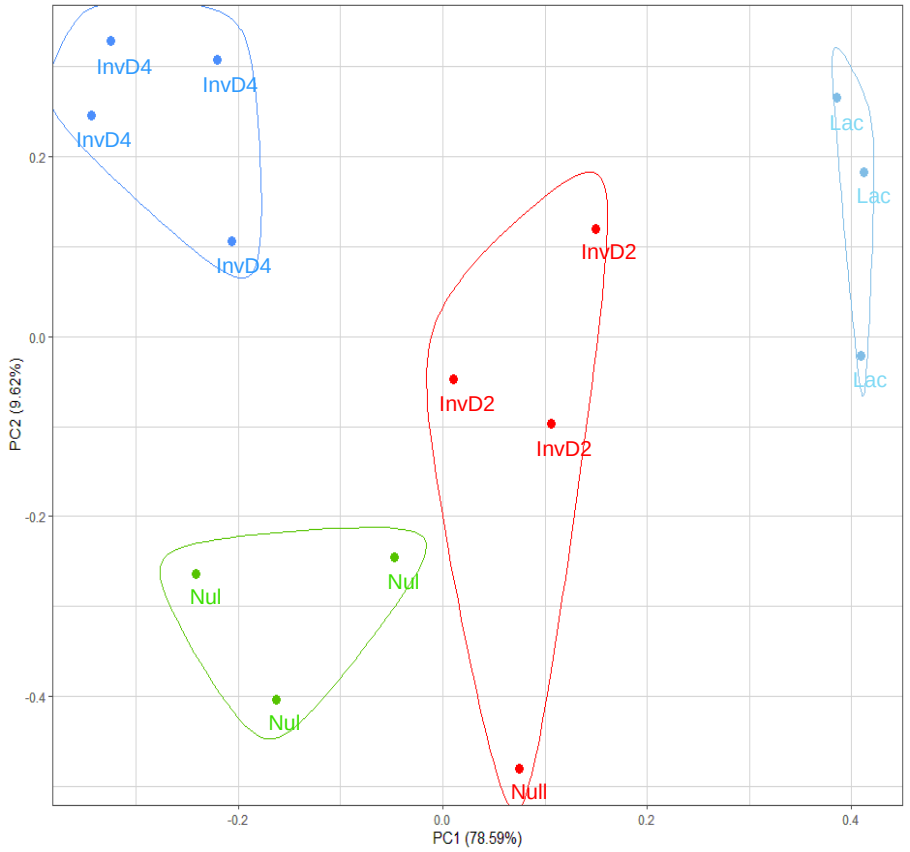
Vitamin D metabolism is altered by reproductive state





Sarah Bernhardt et al, BioRxiv 2024

Expression of 70 CYP450 genes cluster by reproductive state



Summary

- Proximity to recent childbirth predicts metastasis
- BCLM is increased and liver involution likely contributes
- During liver involution, xenobiotic metabolism is suppressed
- Implications for drug efficacy/toxicity in women with recent childbirth?

Introduction and Background

- Pregnant and post-partum patients with breast cancer face unique physiological changes associated with pregnancy that require the coordinated care of several specialists to manage.
- About 3% of women with newly diagnosed breast cancers are pregnant, and the incidence of breast cancer diagnosed in pregnancy (PrBC) and breast cancer diagnosed post-partum (PPBC) is rising [1][2].
- There is a need to identify unmet needs of these patients, especially as younger breast cancer patients often present with more progressed disease. We aimed to characterize the barriers to care and unmet needs among women with PrBC and PPBC.

Methods & Cohort Characteristics

- A retrospective study was conducted to evaluate all female patients diagnosed with breast cancer during pregnancy or within 10 years.
- EMR records from 2015 to 2024 were reviewed from UT Southwestern Medical Center and Parkland Health and Hospital System.
- Data on clinical presentation, demographics, and establishment at various specialty clinics (including oncology, maternal fetal medicine, mental health, and cardiology) were gathered.

Characteristic	Cohort (n=71)
Age, years, mean (range)	36 (21-54)
Diagnosis of Breast Cancer	
During pregnancy	23 (32.4%)
Within 1-year post-partum	5 (7.0%)
Between 1 to 5 years post-partum	25 (35.2%)
Between 5 to 10 years post-partum	18 (25.3%)
Insurance status	
Medicare or Medicaid	4 (5.6%)
Private	43 (60.6%)
Uninsured	24 (33.8%)
Race/Ethnicity	
White or Caucasian	29 (40.8%)
Black or African American	17 (23.9%)
Hispanic	18 (25.3%)
Other	7 (9.8%)

Health Outcomes and Delays in Care

- Among both PrBC and PPBC patients, the mean time from date of breast biopsy to establishment with a medical oncologist was 32.5 days.
- Among PrBC patients, the mean time from date of breast biopsy to establishment with a maternal fetal medicine specialist was 42.7 days.
  - 15 (65.2%) PrBC patients experienced at least one maternal or fetal complication during pregnancy. Complications included gestational hypertension, gestational diabetes, pre-eclampsia, fetal anatomic abnormalities, and inviable pregnancies.
- Among PPBC patients, the mean (SD) time from delivery to biopsy date was 4.1 (2.6) years.
  - Ten (14%) PPBC patients had subsequent pregnancies after initiating chemotherapy.
  - Seven (70%) of these pregnancies resulted in at least one complication.

Unique and Unmet Patient Needs

- Forty (56.3%) patients were treated with cardio-toxic anthracyclines or immunotherapy such as trastuzumab.
  - Thirty-two (80%) obtained an echocardiogram prior to therapy
  - Only 12 (30%) established care with a cardiologist
- Thirty (42%) patients sought out care with a psychologist or psychiatrist for anxiety and depression specifically related to pregnancy and breast cancer diagnosis.

- Of PPBC patients, 16 (33.3%) were unaware of infertility risk with chemotherapy or had no documented conversation regarding fertility preservation and were never prescribed fertility preservation medications.

Conclusions and Next Steps

- We characterize a significant delay in the time from diagnosis to establishment with specialists for PrBC and PPBC patients.
- There is a need for improved rates of echocardiogram completion and cardio-oncology establishment to better monitor the cardiovascular risks.
- We plan to create a multidisciplinary team composed of breast medical and surgical oncology, cardio-oncology, MFM, fertility, and psycho-oncology specialists to help address each of these unmet needs and barriers to care.
- Our hospital system is also creating a role for a patient navigator who will help with patient transportation to clinics as well as sharing information about fertility preservation and mental health resources.
